## SPECIFICATION

To all whom it may concern:

Be It Known, That I, DAVID E. BOSTDORF, of Mount Joy, PA, have invented certain new and useful improvements in OFFSET DIECUT STACK, of which I declare the following to be a full, clear and exact description:

**OFFSET DIECUT STACK**

1

2

3 **BACKGROUND OF THE INVENTION**

4

5 **[0001]** The present invention relates generally to stationery products, and, more specifically,  
6 to die cut sheets.

7 **[0002]** Stationery products are typically manufactured in large quantities from a large roll of  
8 suitable material defining a web. The web is transported along a running axis for producing  
9 therein individual sheets for the desired product. The different types of sheets are innumerable  
10 and vary in material composition, configuration, and size as desired for a particular application.

11 **[0003]** Typical sheets are rectangular and may include continuous diecuts, lines of  
12 perforations, micro-perforations, fold lines, and printing thereon as desired. The sheets may be  
13 single ply without a liner, or may be double ply with a liner. The liner is typically a silicone  
14 release liner which protects pressure sensitive adhesive on the back side of the face ply. The  
15 face ply is typically diecut to form individual pressure sensitive labels which are ubiquitous in  
16 the stationery industry.

17 **[0004]** Single ply sheets include the ubiquitous printing paper manufactured in various sizes  
18 for various uses. Printing paper may have various configurations for specialty applications for  
19 various commercial or consumer applications.

20 **[0005]** In one commercial application a single sheet includes diecuts extending therethrough,  
21 and therefore a stack of such diecut sheets includes identical diecuts aligned together  
22 throughout the entire stack. Since the diecuts extend through the individual sheets they  
23 necessarily provide a continuous cut through the stack of sheets. Since the diecut line is a local  
24 interruption in the otherwise smooth and continuous surface of the sheet, the stacked diecuts  
25 may snag or lock together leading to difficulties in sheet feeding.

26 **[0006]** For example, a stack of sheets is typically loaded into the storage tray of a printer, and  
27 the printer includes a pick up mechanism, such as friction rollers, which remove individual  
28 sheets from the stack in turn. If the diecut in one sheet snags the diecut in the next sheet during  
29 the feeding process in the printer, the feeding mechanism may not be able to separate one sheet

1 interlocked with the next sheet by the aligned diecuts, or may separate the sheets but may cause  
2 undesirable skewing of the initially snagged sheet being fed.

3 [0007] The misfeeding of sheets in printers or copiers is a common problem known to all, and  
4 typically occurs due to friction between the stacked sheets rendered worse under high humidity  
5 conditions. Sheet feeding mechanisms are available in various configurations and complexity  
6 for feeding individual sheets and avoiding multiple sheet feeding in the printer or copier.  
7 Although successive sheets may be separated during the feeding process, excess friction  
8 therebetween may nevertheless cause undesirable misfeeding or skewing of the sheets through  
9 the printing feed path.

10 [0008] Sheets having diecuts extending completely therethrough increase the possibility of  
11 undesirable interlocking between the sheets formed in a stack or vertical lamination thereof.  
12 The possible interlocking effects of the diecuts depends on the configuration, size, and location  
13 thereof in the individual sheets which may cause interlocking or snagging during the feeding  
14 process in a printer.

15 [0009] In one exemplary configuration, a hotel folio comprises a single ply rectangular sheet  
16 of heavy paper containing therein a diecut band through which a magnetic room key card may  
17 be inserted and retained in a cooperating tab formed by a semicircular diecut. The folios are  
18 provided to the hotel in a stack thereof which typically includes preprinted information thereon  
19 regarding the hotel and its services, and may also be post-printed at the time of reception for  
20 adding additional information thereto.

21 [0010] Since the card key receptacle is defined by multiple diecuts, the multiple diecuts  
22 increase the possibility of interlocking of the sheets in the printer, which in turn increases the  
23 possibility of misfeeding or skewing of the sheets during the check-in procedure. Such misfeed  
24 of folio sheets is undesirable because it delays the check-in process and is inconvenient.

25 [0011] Accordingly, it is desired to provide an improved stack of sheets reducing or  
26 eliminating the possibility of interlocking of the diecuts therein.

1 BRIEF SUMMARY OF THE INVENTION

2

3 [0012] A stack of alternating sheets includes repeating diecuts offset among the sheets. The  
4 sheets may be made from a continuous web using a die to cut the repeating diecuts along the  
5 running axis of the web. Individual sheets are cut from the web and stacked with the diecuts  
6 offset from each other in turn. The stack of sheets may be loaded into a printer and fed  
7 individually therethrough, with the offset diecuts preventing interlocking therebetween.

8

9 BRIEF DESCRIPTION OF THE DRAWINGS

10

11 [0013] The invention, in accordance with preferred and exemplary embodiments, together  
12 with further objects and advantages thereof, is more particularly described in the following  
13 detailed description taken in conjunction with the accompanying drawings in which:

14 [0014] Figure 1 is a method flowchart illustrating use of an offset diecut stack of sheets in a  
15 printer.

16 [0015] Figure 2 is a flowchart illustrating an exemplary method of making the stack of sheets  
17 illustrated in Figure 1 from a traveling web.

18 [0016] Figure 3 is an enlarged view of a portion of the web illustrated in Figure 2 showing a  
19 preferred form of the diecut offset in the stack of sheets.

20

21 DETAILED DESCRIPTION OF THE INVENTION

22

23 [0017] Illustrated in Figure 1 is a stack of alternating flat sheets 10a,b configured for use in a  
24 conventional printer 12, such as a laser printer or inkjet printer. The stack may have any  
25 suitable number of sheets therein typically including hundreds thereof, and is suitably loaded  
26 into a storage drawer of the printer 12.

27 [0018] The printer is suitably joined to a conventional computer (not shown) which controls  
28 the printing thereof, and the printer is configured for feeding individual sheets through the

1 printer from the stack stored in the drawer thereof. Any desired print 14 may be printed on the  
2 individual sheets fed through the printer in a conventional manner.

3 **[0019]** The stack of sheets illustrated in Figure 1 has corresponding or repeating diecuts 16  
4 which are offset between the adjoining or adjacent sheets, or among the entire stack of sheets.  
5 In this way, the respective diecuts 16 are not aligned with each other from sheet to sheet in the  
6 stack for preventing undesirable interlocking thereof which might lead to misfeeding in the  
7 printer.

8 **[0020]** Figure 2 illustrates an exemplary method of making the stack of sheets 10a,b  
9 illustrated in Figure 1 which commences with a large supply roll 10r of the desired sheet  
10 material having any conventional composition including paper or synthetics as desired. The  
11 roll is mounted in a conventional apparatus which includes suitable means for unwinding a  
12 continuous web 10w from the supply roll.

13 **[0021]** A roller die 18 is mounted on one side of the web and cooperates with a roller anvil 20  
14 mounted on the opposite side of the web for die cutting the web 10w to form therein the  
15 repeating diecuts 16 along the longitudinal or running axis of the web being unwound from the  
16 roll. The roller die 18 is conventional except for the specific placement of the cutting edges or  
17 knives 24 thereon for effecting the offset of the corresponding diecuts 16 in turn as the die rolls  
18 along with the longitudinal transport of the continuous web 10w.

19 **[0022]** The apparatus illustrated in Figure 2 further includes conventional means in the form  
20 of slitting knives for cutting the web, with each of the sheets having corresponding diecuts  
21 offset from the next successive sheet in the web.

22 **[0023]** The individual sheets are suitably cut from the common web in a conventional manner  
23 and stacked in corresponding groups typically including hundreds of alternating sheets having  
24 the offset diecuts therein. For example, a typical stack of sheets for commercial application  
25 may include a box of about 2,000 or 2,500 sheets for subsequent use by the intended customer.

26 **[0024]** Figure 3 illustrates an enlarged portion of the web 10w shown in Figure 2 wherein the  
27 individual diecuts, designated 16a,b,c, are offset from each other laterally or transversely to the  
28 running axis of the web. For example, the pattern of diecuts 16a,b,c in the first sheet 10a is  
29 laterally offset from the edge of the web by a predetermined offset A, with a different

1 predetermined offset B in the next sheet 10b in turn. The different offsets, A,B ensure that the  
2 respective diecuts are not aligned with each other in the resulting stack of sheets to prevent  
3 interlocking of the stacked sheets by the repeating diecuts.

4 [0025] The difference between the two offsets A,B may be about 6 mm, for example, but may  
5 be larger or smaller as desired, with the minimum difference between the two offsets being the  
6 minimum practical value for preventing alignment of the repeating diecuts which could cause  
7 interlocking therebetween. The minimum difference in offsets A-B between the repeating  
8 diecuts is a function of the positional accuracy of the forming the diecuts in the traveling web  
9 10w using the rotating die 18, and the configuration and orientation of the repeating diecuts.

10 [0026] The typical supply roll 10r illustrated in Figure 2 is commercially available in standard  
11 sizes from which one or more of the individual sheets may be formed across the running width  
12 thereof transversely to the running axis 22. In the exemplary embodiment illustrated in Figure  
13 2, the conventional slitting knives are provided for slitting the web 10w along the running axis  
14 to form three identical smaller webs, each producing a series of the sheets 10a,b with the diecuts  
15 16 repeating both along the longitudinal or running axis of the web as well as transversely  
16 across the width of the web for the three smaller webs produced from the slitting operation.

17 [0027] In this way, three slit webs may be produced from the common larger web, followed  
18 in turn by conventional cutting of the sheets from the three slit webs. The individual flat sheets  
19 10a,b formed from the slitting and cutting operations are then suitably stacked in one or more  
20 groups, such as the three groups illustrated in Figure 2. In each of the stacks illustrated in  
21 Figure 2, the sheets are alternately stacked with the corresponding different offsets A,B.

22 [0028] The basic production of cut sheets with diecuts therein is conventional whether made  
23 from a single small web or from a larger web slit into two or more smaller webs. The  
24 conventional roller die includes cutting edges for the desired diecuts which produces identical  
25 diecuts in identical cut sheets both along the running axis of the web as well as transversely  
26 across the web for maximizing the production of the sheets in the manufacturing process.

27 [0029] Similarly, the cut sheets 10a,b illustrated in Figures 1-3 have identical configurations  
28 for the intended products therefor, except for the diecuts thereof offset among the sheets to  
29 prevent undesirable interlocking therebetween.

1 [0030] In the enlarged view of Figure 3, the individual flat rectangular sheets 10a,b alternate  
2 successively over the height of the stack. The adjoining or touching sheets 10a,b have  
3 corresponding diecuts 16 extending completely through each sheet, and are preferably disposed  
4 inboard from the respective perimeters of the sheets at the different offsets A,B from the sheet  
5 perimeters. The two configurations of the sheets are designated 10a and 10b to conform with  
6 the corresponding offsets A and B of the diecut patterns therein.

7 [0031] The diecuts 16 may be singular in each sheet, or may be multiple as illustrated in the  
8 exemplary embodiment of Figure 3 in which three different diecuts are used in an identical  
9 pattern in each sheet, and designated 16a, 16b, and 16c. The repeating cut sheets are illustrated  
10 in Figures 1 and 2 additionally with the reference letters A and B shown thereon for improving  
11 the correspondence with the detailed view illustrated in Figure 3.

12 [0032] In Figure 3, the corresponding diecuts 16a,b,c of each successive sheet 10a,b repeat  
13 from sheet to sheet along the web, but are simply laterally offset from each other by the  
14 difference in lateral offset A-B from the perimeter of the sheets. In this way the individual  
15 sheets 10a,b may remain identical except for the diecuts themselves, which themselves are  
16 identical from sheet to sheet, but simply offset slightly from sheet to sheet. The slight offset  
17 required from sheet to sheet to prevent undesirable interlocking of the stacked sheets may be as  
18 little as a few millimeters between corresponding diecuts, which would not be perceptible to the  
19 user unless carefully examined. Accordingly, for all intents and purposes the sheets in the stack  
20 are practically identical while eliminating or reducing the potential interlocking problem of  
21 otherwise aligned diecuts.

22 [0033] As shown in Figure 3, the repeating diecuts in the stack of sheets are offset from each  
23 other in any two adjoining or adjacent sheets 10a,b, but aligned with each other in the next  
24 successive sheets. Since the two different offsets A,B define only two different configurations  
25 of the sheets 10a,b, the different sheets 10a,b are stacked alternately in succession for the entire  
26 stack, with the diecuts in one sheet being offset from both next sheets above and below that  
27 sheet, yet aligned with the next successive sheets above and below those adjacent sheets. In  
28 other words, the diecut offsets change and repeat from sheet to sheet between the offsets A and  
29 B repeating successively over the entire stack.

1 [0034] In this way, for the two-configuration design of the sheets 10a,b, the two offsets A,B  
2 repeat in successive sheets and alternate in turn. If desired, three or more different offsets could  
3 be used instead of the two different offsets A,B and repeat in any suitable manner throughout  
4 the stack of sheets.

5 [0035] In the exemplary embodiment illustrated in Figures 1-3, the adjoining sheets 10a,b in  
6 the stack have corresponding identical patterns of multiple diecuts 16a,b,c offset from each  
7 other from sheet to sheet by corresponding lateral offsets A,B from the sheet perimeters. Since  
8 the pattern of three diecuts 16a,b,c is identical from sheet to sheet, the diecut patterns are offset  
9 laterally from each other by the corresponding difference in offsets A-B. In other words, each  
10 of the multiple diecuts 16a,b,c has a correspondingly larger offset from the edge of the sheet,  
11 yet the difference in offset between adjacent sheets is preferably identical for each diecut.

12 [0036] As illustrated in most detail in Figure 3, each of the exemplary diecut patterns includes  
13 an arcuate diecut 16a in the form of a semicircle, and one or more straight diecuts 16b,c spaced  
14 laterally therefrom along the transverse width of the web. The arcuate and straight diecuts  
15 repeat from sheet to sheet along the running axis of the web, but have common different offsets  
16 A,B from sheet to sheet to ensure that the corresponding diecuts are not aligned with each other  
17 in the resulting stack of sheets.

18 [0037] In the exemplary embodiment illustrated in Figure 3, each of the diecut patterns  
19 includes a pair of straight and parallel diecuts 16b,c which define therebetween a small band 26  
20 spaced laterally from the arcuate diecut 16a. Correspondingly, the arcuate diecut 16a itself  
21 defines a semicircular tab 28.

22 [0038] This configuration of the sheets 10a,b defines an exemplary hotel folio as illustrated in  
23 Figure 1 in which a conventional flat magnetic card key 30 may be inserted through the two  
24 straight diecuts defining the band 26 down into the arcuate diecut defining the tab 28. The band  
25 and tab thusly capture or retain the key in the sheet folio.

26 [0039] In this configuration of the folio sheets 10a,b illustrated in Figures 1 and 3, each sheet  
27 includes three sections defining corresponding pages 32,34,36. The diecut pattern is preferably  
28 disposed in the center page 34 between the adjoining front and back pages 32,36.

1 [0040] Figure 1 illustrates an exemplary use of the hotel folio sheets 10a,b in which the stack  
2 of sheets is loaded in the printer, and fed individually therethrough for printing any desired print  
3 thereon. The stack of sheets 10a,b is loaded in the printer with the diecuts 16 being offset  
4 laterally or transversely to the feeding path or direction through the printer. In this way, the  
5 straight diecuts are aligned with the feeding direction of the printer, and the arcuate diecuts are  
6 offset transversely therewith.

7 [0041] The individual folio sheets may therefore be individually transported through the  
8 printer without interlocking of the stacked diecuts, and accurately printed thereon in a single  
9 pass. The so printed sheet 10a is then suitably folded by hand, for example, in three  
10 overlapping pages 32,34,36, with the diecuts 16 being disposed in the center page between the  
11 front and back pages.

12 [0042] As indicated above, Figure 3 illustrates two basic forms of the diecuts being arcuate  
13 and straight, and arranged in one orientation relative to the running axis of the web, which  
14 corresponds with the feeding axis through the printer 12 of Figure 1. In order to avoid  
15 undesirable interlocking of aligned diecuts, straight diecuts may be offset laterally apart and  
16 generally normal thereto with a relatively small offset therebetween. In this way, the offset of  
17 the straight diecuts is barely perceptible to the intended user without careful observation.

18 [0043] Straight diecuts could also be offset along their longitudinal axes, but this would  
19 require an offset as least as large as the length of the individual diecut to avoid any overlap  
20 therebetween. This may be acceptable in some configurations, or the longitudinal offset may be  
21 smaller and permit some overlap or alignment of the straight diecuts.

22 [0044] The straight diecuts could also be offset by rotation from sheet to sheet, and therefore  
23 aligned with each other at a single crossing point. This offset may be acceptable in certain  
24 configurations, but might be more visible to the user and aesthetically undesirable.

25 [0045] In contrast, the semicircular arcuate diecut 16a illustrated in Figure 3 would require  
26 relatively large rotary offset for minimizing or preventing alignment thereof between the sheets,  
27 whereas the small lateral offset is sufficient from sheet to sheet. The offset of the arcuate diecut  
28 16a may be in any suitable direction either transversely to the running axis of the web, or along

1 the running axis of the web, or in any intermediate orientation therebetween as desired for the  
2 specific product intended.

3 [0046] Since the ubiquitous continuous diecut is found in arcuate or straight forms in various  
4 cut sheet products, such diecuts may be conveniently laterally offset from each other in any  
5 suitable manner from sheet to sheet in the corresponding stack thereof for preventing diecut  
6 interlock. The amount of offset may vary as desired and may be translation only, rotary only,  
7 or a combination of both as desired for the particular configuration of the diecuts and intended  
8 product.

9 [0047] In the exemplary hotel folio cut sheets illustrated in Figure 1, the straight and arcuate  
10 diecuts are symmetrically positioned in the center page 34 and may be conveniently offset  
11 laterally thereon between the opposite edges of the sheet without compromising the functional  
12 or aesthetic attributes of the sheet. The small, exemplary 6 mm, lateral offset of the diecut  
13 patterns from sheet to sheet in the stack is practically imperceptible to the intended user, with  
14 the cut sheets being otherwise identical.

15 [0048] The offset diecut in the stack of sheets may be used wherever desired for eliminating  
16 or reducing the possibility of sheet interlocking from aligned diecuts, and therefore has  
17 innumerable applications.

18 [0049] While there have been described herein what are considered to be preferred and  
19 exemplary embodiments of the present invention, other modifications of the invention shall be  
20 apparent to those skilled in the art from the teachings herein, and it is, therefore, desired to be  
21 secured in the appended claims all such modifications as fall within the true spirit and scope of  
22 the invention.

23 [0050] Accordingly, what is desired to be secured by Letters Patent of the United States is the  
24 invention as defined and differentiated in the following claims in which I claim:
